

Gasutsläpp från en processanläggning på ett oljeraffinaderi.

901129 MARS 1990_23

Olyckan inträffade på en kolonn för separation av C3-kolväten från C4-kolväten på ett oljeraffinaderi. En mindre ventil blockerades på något vis av natriumhydroxid. Blockeringen avlägsnades genom att tryckluft blåstes genom ventilen, men sedan kunde ventilen inte stängas igen. Flytande kolväten, LPG, strömmade ut genom ventilen. Denna mängd kolväten antändes inte och kunde skingras utan problem. Flödet omdirigerades till facklan där en annan blockering orsakade att rörledningen till facklan lossnade, dock utan att mera kolväten släpptes ut. Fabriken försattes i katastrofberedskap.

A Occurrence Full Report

country: FA **ident key:** 1990_023_01

1 Type of Accident

remarks: The initiating event was the release of LPG through a 50 mm valve connected to a depropaniser reboiler (code 1101). The LPG released dispersed without igniting. In order to reduce the amount of LPG escaping, the interconnecting depropaniser... see Appendix Full Report A / type of accident

2 Dangerous Substances

remarks: The LPG (propane, propylene, butane, butylene) was released only through the drain valve on the depropaniser reboiler. No LPG was released the displaced flareline, although the potential was present. No data are available about the amounts ... see Appendix Full Report A / dangerous substances

3 Source of Accident

illustration: - not applicable -

remarks: The accident occurred in a process plant of a petroleum refinery (code 2002). The plant included a depropaniser column, polypropylene/propane splitter columns and a flareline. The accident occurred during the maintenance of a blocked drain ... see Appendix Full Report A / source of accident - remarks

5 Discussion about Response

- not applicable -

Appendices for the FA / 1990_023_01 report

Appendix Short Report / description of accident types:

An operator disconnected a drain assembly connected to the depropaniser reboiler until it was remained only a partially opened but blocked 50mm valve (from the Original Report it is not fully clear if it was a 50mm or a 15mm valve). The blockage was caused by caustic soda and the operator played steam over the valve to clear the blockage. The blockage was cleared but the operator was unable to close the gate valve due to caustic soda and LPG released at high temperature and pressure (the disconnection of the pipework was not done in accordance with the sites standing instructions). In order to reduce the pressure in the depropaniser to minimise the amount of LPG escaping from the 50mm valve, a 406mm pneumatically operated depressurizing valve was opened. This valve, with a rated capacity of 13.375 tons per minute, was

designed to depressurize the interconnected depropaniser and polypropylene splitter columns in 15 minutes via a 762mm line into the main 910mm flareheader. After the depressurizing valve was opened, the 50mm gate valve connected to the depropaniser was closed by an operator wearing breathing apparatus. The LPG released was safely dispersed. The emergency depressurising valve was open for 2'19". At a low point in the 762mm line to the main flareheader described above there was located a small (254mm diameter, 600mm high) sump. At the bottom of this sump there was a 38mm diameter pipe to drain accumulated liquid into a nearby vessel. The liquid accumulated in this vessel was automatically pumped away. The sump was however blocked with debris and this allowed a large amount of liquid (about 30 m³) to accumulate in the 762mm line. The escaping gas from the depressurizing valve caused this liquid to be dispersed down the flareline and the forces generated caused about 100m of 762mm line to be displaced, falling approximately 10 metres to the ground. The pipeline buckled and in a few points there were some crackings. In one point a crack was found to have propagated through the 77% of the 10mm nominal thickness of the pipeline wall. The pipeline did not however failed and no LPG was released from this source.

Appendix Short Report / description of substances involved:

- Propane (C.A.S. CODE: 74-98-6): amount involved = not known.
- Propylene (C.A.S. CODE: 115-07-1): amount involved = not known.
- Butane (C.A.S. CODE: 106-97-8): amount involved = not known.
- Butylene (C.A.S. CODE: 25167-67-3): amount involved = not known.

N.B. The LPG (propane, propylene, butane, butylene) was released only through the drain valve on the depropaniser reboiler. No LPG was released the displaced flareline, although the potential was present.

Appendix Short Report / description of immediate sources:

The accident occurred in a process plant of a petroleum refinery. The plant included the depropaniser column (to separate C3 and C4), the polypropylene/propane splitter columns and the flare system. The LPG release occurred during the maintenance of a blocked drain valve on the depropaniser reboiler. The depropaniser reboiler was operating at about 104°C and 18.1 barg.

Appendix Short Report / description of suspected causes:

INITIATING EVENT AND CONSEQUENCES:

The initiating event was the release of LPG through 15mm drain valve (initially blocked by caustic soda) connected to the depropaniser reboiler. The operator was unable to close the valve after its blockage was cleared out by means of steam. In order to reduce the amount of released LPG, the depropaniser and polypropylene splitter columns were depressurised via an emergency depressurising valve to a flareline. A blockage in the flareline resulted in its displacement.

CAUSES:

The initiating event was caused by the blockage of a drain valve by caustic soda. The disconnection of the pipework was not done in accordance with the sites standing procedures that, however, were inadequate for clearing a pipe blockage. The flareline displacement was caused by the failure to maintain the line free of blockages (no written procedures were instituted to avoid it and, besides, the design of the flareline drainage arrangements made its maintenance difficult).

Appendix Short Report / description of emergency measures taken:

INTERNAL TO THE ESTABLISHMENT:

The emergency depressurization of the interconnected depropaniser and polypropylene splitter columns was activated in order to minimize the amount of LPG released from the drain valve. After the activation of the emergency depressurization, the drain valve was closed by an operator wearing breathing apparatus. Besides, as precautionary measures:

- all the areas in the vicinity of the plant were evacuated;
- the internal fire brigade was alerted and attended incident;
- mobile and fixed fire monitors were set-up downwind of the damaged sections of flareline;
- roads in the area were closed;
- the county fire brigades were called.

Appendix Short Report / description of immediate lessons learned:

MEASURES TO PREVENT ANY RECURRENCE OF SIMILAR ACCIDENTS:

After the accident, the following measures were established:

- 1- procedures with regard to the drainage of caustic soda etc, from LPG containing installations have been reinforced;
- 2- the flareline was reconstructed and the design for the liquid removal from the line has been improved such that its blockage is no longer foreseeable;
- 3- written maintenance procedures have been instituted.

Appendix Full Report A / type of accident:

The initiating event was the release of LPG through a 50 mm valve connected to a depropaniser reboiler (code 1101). The LPG released dispersed without igniting. In order to reduce the amount of LPG escaping, the interconnecting depropaniser and polypropylene splitter columns were depressurized to a flareheader. Due to a line blockage, the flareline displacement occurred. The flareline did not however fail and no LPG was released from this source.

Appendix Full Report A / dangerous substances:

The LPG (propane, propylene, butane, butylene) was released only through the drain valve on the depropaniser reboiler. No LPG was released the displaced flareline, although the potential was present. No data are available about the amounts of the substances released during the accident.

Appendix Full Report A / source of accident - remarks:

The accident occurred in a process plant of a petroleum refinery (code 2002). The plant included a depropaniser column, polypropylene/propane splitter columns and a flareline. The accident occurred during the maintenance of a blocked drain valve on the depropanizer reboiler (code 4010). The depropaniser was operating at 104 °C and 18.1 barg.

Appendix Full Report A / causes of major occurrence:

The drain valve on the depropaniser reboiler was blocked by caustic soda (code 5108). The disconnection of the drain assembly was not done in accordance with the (however inadequate) procedures (codes 5303 and 5401). Besides, the flareline displacement occurred due to the failure to maintain the line free of blockages (code 5108), due to the lack of written procedures (code 5303) and to the inadequate design of the flareline drainage arrangements that had made maintenance difficult (code 5308).

Appendix Full Report B / area concerned - remarks:

Though all the areas in the vicinity of the plant were evacuated, in the Original Report there is no evidence of significant effects outside the installation.

Appendix Full Report B / people:

No data are available about the number of people involved in the accident.

Appendix Full Report B / ecological harm:

In the Original Report there is no evidence of significant ecological harms. This is due to the low ecotoxic risks of the substances involved in the accident.

Appendix Full Report B / material loss:

The cost of reinstating the flareline was about 980,000 pounds.

Appendix Full Report B / disruption of community life:

In the Original Report there is no evidence of significant effects outside the installation.

Appendix Full Report C / lesson learned - prevent:

After the accident, the following measures were established:

- 1- the operating procedures with regard to the drainage of caustic soda, etc. from LPG containing installations have been reinforced;
- 2- the flareline has been reconstructed and the design for the liquid removal from the line has been improved such that its blockage is no longer foreseeable;
- 3- written maintenance procedures have been instituted.

Appendix Full Report C / lesson learned - references:

Some calculations were carried out in order to evaluate the overpressure and consequential effects in case the flareline had really failed. These calculations, however, involved some speculations in evaluate the rate of gas release, the gas dispersion, the extent of the confinement, etc.
